

# DVS® PREMIUM CONNECT – SUMMER VENTILATION

Ventilate your home with fresh filtered air from outside the roof space.

It can get very hot in the roof space in Summer, so the DVS® Premium Connect - Summer Ventilation system will draw a continuous supply of fresh, filtered air from outside of the roof space. Helping to keep your home fresher, and at the same time effectively filtering pollens, which can cause devastating symptoms for people who suffer from allergies or respiratory illnesses.

## What is it & what does it do?

A continuous supply of fresh, filtered air is drawn from outside of the roof space when the roof space itself becomes too hot. This allows you to make better use of your DVS® during summer, ventilating with fresh air when you're not home to open the windows.

## How does it work?

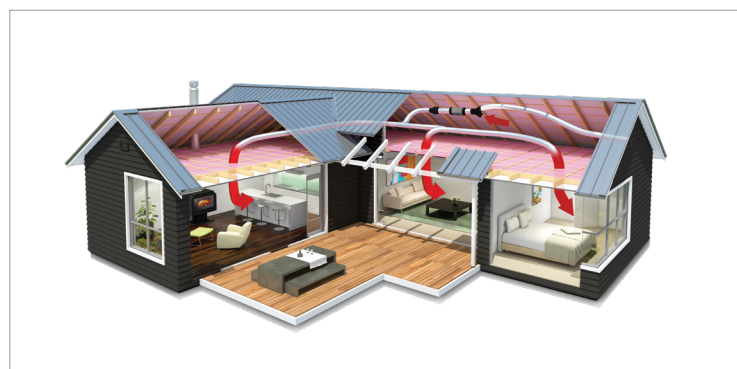

Additional equipment is installed in the roof space of your home and an intake vent is installed on the outside of your home.

The DVS® continually measures the temperatures in your home (at the control panel), in the roof space and at the outside vent. Then, depending on how you have chosen to have your system set up, the DVS® will stop taking air from the roof space and instead take air from outside the house via the outside vent.

The DVS® is installed with insulated ducting to prevent any significant heat loss or gain in the system.

## DVS® Controller

The controller offers personal control of your home environment, all through an easy, simple to use interface. Your system will be configured for you, and the airflow and settings individually calibrated to the size of your home to run automatically. However, you will be able to easily fine tune the system settings and adjust how your summer ventilation component operates.
